Unconstrained Face Recognition: Identifying a Person of Interest from a Media Collection

Lacey Best-Rowden, Hu Han, Member, IEEE, Charles Otto, Brendan Klare, Member, IEEE, and Anil K. Jain, Fellow, IEEE

Abstract—As face recognition applications progress from constrained sensing and cooperative subjects scenarios (e.g., driver's license and passport photos) to unconstrained scenarios with uncooperative subjects (e.g., video surveillance), new challenges are encountered. These challenges are due to variations in ambient illumination, image resolution, background clutter, facial pose, expression, and occlusion. In forensic investigations where the goal is to identify a “person of interest,” often based on low quality face images and videos, we need to utilize whatever source of information is available about the person. This could include one or more video tracks, multiple still images captured by bystanders (using, for example, their mobile phones), 3D face models, and verbal descriptions of the subject provided by witnesses. These verbal descriptions can be used to generate a face sketch and provide ancillary information about the person of interest (e.g., gender, race, and age). While traditional face matching methods take single media (i.e., a still face image, video track, or face sketch) as input, our work considers using the entire gamut of media collection as a probe to generate a single candidate list for the person of interest. We show that the proposed approach boosts the likelihood of correctly identifying the person of interest through the use of different fusion schemes, 3D face models, and incorporation of quality measures for fusion and video frame selection.

Index Terms—Unconstrained face recognition, uncooperative subjects, media collection, quality-based fusion, still face image, video track, 3D face model, face sketch, demographics

I. INTRODUCTION

As face recognition applications progress from constrained imaging and cooperative subjects (e.g., identity card deduplication) to unconstrained imaging scenarios with uncooperative subjects (e.g., watch list monitoring), a lack of guidance exists with respect to optimal approaches for integrating face recognition algorithms into large-scale applications of interest. In this work we explore the problem of identifying a person of interest given a variety of information source about the person (face image, surveillance video, face sketch, 3D face model and demographic information) in both closed set and open set identification modes.

Identifying a person based on unconstrained face image(s) is an increasingly prevalent task for law enforcement and intelligence agencies. In general, these applications seek to determine the identity of a subject based on one or more probe images or videos, where a top 50 ranked list retrieved from the gallery (for example) may suffice for analysts (or forensic examiners) to identify the subject [1]. In many cases, such a forensic identification is performed when multiple face images and/or a face track1 from a video of a person of interest are available (see Fig. 1). For example, in investigative scenarios, multiple face images of an unknown subject often arise from an initial clustering of visual evidence, such as a network of surveillance cameras, the contents of a seized hard drive, or from open source intelligence (e.g., social networks). In turn, these probe images are searched against large-scale face repositories, such as mug shot or identity card databases.

High profile crimes such as the Boston bombings relied on large amounts of manual labor to identify the person of interest:

"It’s our intention to go through every frame of every video [from the marathon bombings],” Boston Police Commissioner Ed Davis2

While other routine, but high value, crimes such as armed robberies, kidnappings, and acts of violence require similar

1A “face track” is a sequence of cropped face images which can be assumed to be of the same person. We use the terms face track and video track interchangeably in this paper.

2http://www.washingtonpost.com/world/national-security/boston-marathon-bombings-investigators-sifting-through-images-debris-for-clues/2013/04/16/1cabb4d4-a6c4-11e2-b029-8fb7e977ef71_story.html
identifications, only a fraction of the manual resources are available to solve these crimes. Thus, it is paramount for face recognition researchers and practitioners to have a firm understanding of optimal strategies for combining multiple sources of face information, collectively called face media, available to identify the person of interest.

While forensic identification is focused on human-driven queries, several emerging applications of face recognition technology exist where it is neither practical nor economical for a human to have a high degree of intervention with the automatic face recognition system. One such example is watch list identification from surveillance cameras, where a list of persons of interest are continuously searched against streaming videos. Termed as open set recognition, these challenging applications will likely have better recognition performance as unconstrained face recognition algorithms continue to develop and mature [5]. We provide experimental protocols, recognition accuracies on these protocols using COTS face recognition and 3D face modeling algorithms, and an analysis of the integration strategies to improve operational scenarios involving open set recognition.

A. Overview

In forensic investigations, manual examination of a suspect’s face image against a mug shot database with millions of face images is prohibitive. Thus, automatic face recognition techniques are utilized to generate a candidate suspect list. As shown in Fig. 2, forensic investigations using face images typically involve six stages: obtaining face media, preprocessing, automatic face matching, generating a suspect list, human or forensic analysis, and forensic reporting. The available forensic data or media of the suspect may include still face image(s), video track(s), a face sketch, and demographic information (age, gender, and race) as shown in Fig. 3. While traditional face matching methods take a single media sample (i.e., a still face image, video track, or face sketch) as input to generate a suspect list, a media collection is expected to provide more identifiable information about a suspect than a single media. The proposed approach contributes to forensic investigations by taking into account the entire media collection of the suspect to perform face matching and generating a single candidate suspect list.

In this paper we examine the use of commercial off the shelf (COTS) face recognition systems with respect to the aforementioned challenges in large-scale unconstrained face recognition scenarios. First, the efficacy of forensic identification is explored by combining two public-domain unconstrained face recognition databases, Labeled Faces in the Wild (LFW) [2] and the YouTube Faces (YTF) [3], to create sets of multiple probe images and videos to be matched against single gallery images for each subject. To replicate forensic identification scenarios, we populate our gallery with one million operational mug shot images from the Pinellas County Sheriff’s Office (PCSO) database. Using this data, we are able to examine how to boost the likelihood of face

---

3While a closed-set identification system deals with the scenario where the person of interest is always someone in the gallery, and always returns a non-empty candidate list, an open-set identification system allows for the scenario where the person of interest is not enrolled in the gallery, and so can return a possibly empty candidate list [4].

4A more detailed description of this forensic investigation process can be found at: http://www.justice.gov/criminal/cybercrime/docs/forensics_chart.pdf

identification through different fusion schemes, incorporation of 3D face models and hand drawn sketches, and methods for selecting the highest quality video frames. Researchers interested in improving forensic identification accuracy can use this competitive baseline (on public-domain databases LFW and YTF) to provide more objectivity towards such goals.

Most work on unconstrained face recognition using the LFW and YTF databases has been reported in verification scenarios [6], [7]. However, in forensic investigations, it is the identification mode that is of interest, especially the open-set identification scenario where the person on the watch list may not be present in the legacy face databases.

The contributions of this work can be summarized as follows:

- We show, for the first time, how a collection of face media (image, video, 3D model, demographic data, and sketch) can be used to mitigate the challenges associated with unconstrained face recognition (uncooperative subjects, unconstrained imaging conditions), and boost recognition accuracy.
- Unlike previous work that reports results in verification mode, we present results for both open set and closed set identifications which are encountered in identifying persons of interest in forensic and watch list scenarios.
- We present effective face quality measures to determine when the fusion of information sources will help boost the identification accuracy. The quality measures are also used to assign weights to different media sources.
- To demonstrate the effectiveness of media-as-input for the difficult problem of unconstrained face recognition, we utilize a state-of-the-art face matcher and a separate 3D face modeling SDK. We use crowdsourcing to obtain the estimates of gender and race. This allows us to show the contribution of various media components as we incrementally add them as input to the face matching system.

The remainder of the paper is organized as follows. In Section II, we briefly review published methods related to unconstrained face recognition. We detail the proposed face media collection as input, and the media fusion method in Sections III and IV, respectively. Experimental setup and protocols are given in Section V, and experimental results are presented in Section VI. Finally, we conclude this work in Section VII.

II. RELATED WORK

The release of public-domain Labeled Faces in the Wild (LFW) database in 2007 has spurred interest and progress in unconstrained face recognition. The LFW database is a collection of more than 13,000 face images, downloaded from the Internet, of 5,749 different individuals such as celebrities, public figures, etc. [2]. The only constraint on these images is that faces could be detected by the Viola-Jones face detector [8]. Despite this constraint, the LFW database contains significant variations in facial pose, illumination, and expression, and many of the face images are occluded. The LFW protocol consists of face verification based on ten-fold cross-validation, each fold containing 300 “same face” and 300 “not-same face” image pairs.

The YouTube Faces (YTF) database, released in 2011, is the video-equivalent to LFW for unconstrained face matching in videos. The YTF database contains 3,425 videos of 1,595 individuals. The individuals in the YTF database are a subset of those in the LFW database. Faces in the YTF database were detected with the Viola-Jones face detector at 24 fps, and face tracks were included in the database if there were at least 48 consecutive frames of that individual’s face. Similar to the LFW protocol, the YTF verification protocol consists of ten cross-validation folds, each with 250 “same face” and 250 “not-same face” track pairs. Figure 4 shows example face images and video tracks from the LFW and YTF databases for one particular subject. In this paper, we combine these two databases to evaluate the performance of face recognition on unconstrained face media collections.

We provide a summary of related work on unconstrained face recognition, focusing on various face media matching scenarios in Table I (we emphasize that most prior work has evaluated unconstrained face recognition methods in the verification mode). While fully automated face recognition systems are able to achieve ~99% face verification accuracy at 0.1% False Alarm Rate (FAR) in constrained imagery and cooperative subject conditions [25], face recognition in unconstrained environments remains a challenging problem [11]. These methods can be grouped into two main categories: single face media based methods and face media collection based methods.

Single media based methods focus on the scenario where both the query and target instances contain only one type of

<sup>1</sup>There are totally 10 folds, and the final performance is an average across the 10 folds. <sup>2</sup>About 40 different methods (e.g., [19]–[24]) have reported performance on the LFW database, but all of them can be grouped in to single media (single image vs. single image) based UFR method. Due to the limited space, we only list the most recently reported performance for each testing protocol in this table. Similarly, methods that have reported results on the YTF database are also single media (single video vs. single video) based UFR method. <sup>3</sup>Strict vs. outside: no outside training data is used vs. outside training data is used in the face alignment, feature extraction, or face matching algorithm. <sup>4</sup>The performance of the proposed method reported in this table is the Rank-1 identification accuracy.

face media, such as a still image, video track, or 3D image. However, the query and target instances can be different media types, such as single image vs. single video. These methods can be effective in unconstrained illumination and expression variation conditions but can only handle limited pose variations. For example, while ∼97% TAR at 0.1% FAR<sup>9</sup> has been reported in MBGC v2.0 unconstrained vs. unconstrained face matching, under large pose variations, this performance drops

<sup>9</sup>True acceptance rate (TAR) vs. false acceptance rate (FAR) is the metric of choice in face verification scenarios.
to TAR = \~17\% at 0.1\% FAR in MBGCv2.0 non-frontal vs. frontal face matching (see Table I). Such challenges were also observed in single image vs. single image face matching in LFW, and single video vs. single video face matching in YTF and MBGC v2.0 walking vs. walking databases.

These observations suggest that in unconstrained conditions, a single face media sample of, especially “low quality”, may not be able to provide a sufficient description of a face. This motivates the use of face media collection which utilize any media that is available for a probe (or query) instance of a face. One preliminary study is the FRGCv2.0 Exp. 3, where (i) a single 3D face image and (ii) a collection of single 3D image and a single 2D face image were used as queries. Results show that the media collection (2D face and 3D face) improves the face matching performance (79\% TAR for 3D face and 2D face vs. 53\% TAR for just the 3D face at 0.1\% FAR) in unconstrained conditions. It is, therefore, important to determine how we can improve the face matching accuracy when presented with a collection of face media, albeit of different qualities, as probe.

III. MEDIA-AS-INPUT

A face media collection can possibly consist of still face images, face video tracks, a 3D face model, a forensic sketch, and demographic information. In this section, we discuss how we use face “media-as-input” as probe and our approach to media fusion.

A. Still Image and Video Track

Still image and video track are two of the most widely used media in face recognition systems [4]. Given multiple still images and videos, we use the method reported in [18] to match all still images and video frames available for a subject of interest to the gallery mugshot (frontal pose) images using a COTS matcher. The resulting match scores are then fused to get a single match score for either multiple probe images or video(s).

B. 3D Face Models

One of the main challenges in unconstrained face recognition is large variations in facial pose [26], [27]. In particular, out-of-plane rotations drastically change the 2D appearance of a face, as they cause portions of the face to be occluded. A common approach to mitigate the effects of pose variations is to build a 3D face model from a 2D image(s) so that synthetic 2D face images can then be rendered at designated poses (e.g., [28]–[30]).

In this paper, we use a state-of-the-art COTS 3D face modeling SDK, namely CyberExtruder’s Aureus 3D SDK, to build 3D models from 2D unconstrained face images. The 3D face model is used to render a “pose corrected” (i.e., frontal facing) image of the unconstrained probe face images. The pose corrected image can then be matched against a frontal gallery. We also pose correct “frontal” gallery images because even the gallery images can have slight variations in pose as well. Experimental results show that post corrected gallery images improve the identification performance.

![Fig. 5. Pose correction of probe (left) and gallery (right) face images using CyberExtruder’s Aureus 3D SDK. We consider the fusion of four different match scores (s1, s2, s3, and s4) between the original probe and gallery images (top) and synthetic pose corrected probe and gallery images (bottom).](image)

![Fig. 6. Pose corrected faces (b) in a video track (a) and the resulting “consolidated” 3D face model (c). The consolidated 3D face model is a summarization of all frames in the video track.](image)

Given the original and pose corrected probe and gallery images, there are four matching scores that can be computed between any pair of probe and gallery face images (see Fig. 5). We use the score s1 as the baseline to determine whether including scores s2, s3, s4, or their fusion can improve the performance of a COTS face matcher. A face in a video frame can be pose corrected in the same manner. The Aureus SDK also summarizes faces from multiple frames in a video track as a “consolidated” 3D face model (see Fig. 6).

C. Demographic Attributes

In many law enforcement and government applications, it is customary to collect ancillary information like age, gender, race, height, and eye color from the users during enrollment. We explore how to best utilize the demographic data to boost the recognition accuracy. Demographic information such as age, gender and race becomes even more important in complementing the identity information provided by face images and videos in unconstrained face recognition, due to the difficulty of the face matching task.

In this paper, we take the gender and race attributes of each subject in the LFW and YTF face databases as one type of media. Since this demographic information is not available for the subjects in the LFW and YTF face databases, we utilized the Amazon Mechanical Turk (MTurk) crowdsourcing
For gender and race estimation tasks, we submitted 5,749 Human Intelligence Tasks (HITs), with ten human workers per HIT, at a cost of 2 cents per HIT. Finally, a majority voting scheme (among the responses) is utilized to determine the gender (Female or Male) and race (Black, White, Asian or Unknown) of each subject. We did not consider age in this paper due to the large variations in its estimate by crowd workers.

D. Forensic Sketches

Face sketch based identification dates back to the 19th century [33], where the paradigm for identifying subjects using face sketches relied on human examination. Recent studies on automated sketch based identification system show that sketches can also be helpful to law-enforcement agencies to identify the person of interest from mugshot databases [34]. In situations where the suspect’s photo or video is not available, expertise of forensic sketch artists are utilized to draw a suspect’s sketch based on the verbal description provided by the eyewitness or victim. In some situations, even when a photo or video of a suspect is available, the quality of this media can be poor. In this situation also, a forensic sketch artist can be called in to draw a face sketch based on the low-quality face photo or video. For this reason, we also include the face sketch in a face media collection.

We manually selected 21 low-quality (large pose variations, shadow, blur, etc.) videos (one video per subject) from the YTF database (for three subjects, we also included a low quality still image from LFW), and asked two forensic sketch artists to draw a face sketch for each subject in these videos. Examples of these sketches and their corresponding low-quality videos are shown in Figs. 7 and 14.

IV. MEDIA FUSION

Given a face media collection as probe, there are various schemes to integrate the identity information provided by individual media component, such as score level fusion, rank level fusion and decision level fusion [35]. Among these approaches, score level fusion is the most commonly adopted. Some COTS matchers do not output a meaningful match score (to prevent hill-climbing attacks [36]). Thus, in these situations, rank level or decision level fusion needs to be adopted.

In this paper, we match each media (image, video, 3D model, sketch or demographic information) of a probe to the gallery and integrate the scores using score level fusion. Specifically, the score level fusion takes place in two different layers: (i) fusion within one type of media, and (ii) fusion across different types of media. The first fusion layer generates a single score from each media type if its multiple instances are available. For example, matching scores from multiple images or multiple video frames can be fused to get a single score. Additionally, if multiple video clips are available, matching scores of individual video clips can also be fused. Score fusion within the ith face media can be generally formulated as

$$s_i = \tilde{f}(s_{i,1}, s_{i,2}, \cdots, s_{i,n}),$$

where $s_i$ is a single matching score based on $n$ instances of the ith face media type; $\tilde{f}(\cdot)$ is a score level fusion rule; we use the sum rule, i.e., $s = \frac{1}{n} \sum_{i=1}^{n} s_i$, that has been found to be quite effective in practice [18]. Given the match score of each face media type, the next fusion step involves fusing the scores across different types of face media. Again, the sum rule is used and found to work very well in our experiments; however, as shown in Fig. 8, face media for a person of interest can be of different quality. For example, a 3D face model can be corrupted due to inaccurate localization of facial landmarks. As a result, matching scores calculated from individual media source may have different degrees of confidence.

We take into account the quality of individual media type by designing a quality based fusion. Specifically, let $S = [s_1, s_2, \cdots, s_m]^T$ be a vector of the match scores between $n$ different media types in a collection of probe and gallery, and $Q = [q_1, q_2, \cdots, q_m]^T$ be a vector of quality values for the corresponding input media. The final matching score between a probe and a gallery image is calculated by a weighted sum rule fusion

$$s = \sum_{i=1}^{m} q_i s_i = Q^T S,$$

Note that the quality based across-media fusion in (2) can also be applied to score level fusion within a particular face media type (e.g., 2D face images).

In this paper, we have considered five types of media in a collection: 2D face image, video, 3D face model, sketch, and demographic information. However, since only sketches of 21 persons (out of 596 persons that are common in LFW and YTF databases) are available, in most of the experiments, we...
perform the quality-based fusion in (2) based on only four types of media \((m = 4)\). The quality value measures for individual media type are defined as follows.

- **Image and video.** For a probe image, the COTS matcher assigns a face confidence value in the range of \([0, 1]\), which is used as the quality value. For each video frame, the same face confidence value measure is used. The average face confidence value across all frames is used as the quality value for a video track.

- **3D face model.** The Aureus 3D SDK used to build a 3D face model from image(s) or video frame(s) does not output a confidence score. We define the quality of a 3D face model based on the pose corrected 2D face image generated from it. Given a pose corrected face image, we calculate its structural similarity (SSIM) [37] to a set of predefined reference images (manually selected frontal face images). Let \(I_{PC}\) be a pose corrected face image (from the 3D model), and \(R = \{R_1, R_2, \ldots, R_t\}\) be the set of \(t\) reference face images. The quality value of a 3D model based on SSIM is defined as

\[
q(I_{PC}) = \frac{1}{t} \sum_{i=1}^{t} \text{SSIM}(I_{PC}, R_i) \\
= \frac{1}{t} \sum_{i=1}^{t} l(I_{PC}, R_i)^{\alpha} \cdot c(I_{PC}, R_i)^{\beta} \cdot s(I_{PC}, R_i)^{\gamma}
\]

(3)

where \(l(\cdot), c(\cdot),\) and \(s(\cdot)\) are luminance, contrast, and structure comparison functions [37], respectively; \(\alpha, \beta,\) and \(\gamma\) are parameters used to adjust the relative importance of the three components. We use the recommended parameters \(\alpha = \beta = \gamma = 1\) in [37]. The quality value is in the range of [0, 1].

- **Demographic information.** As stated earlier, we collected demographic attributes (gender and race) of each face image using the MTurk crowdsourcing service with ten MTurk workers per task. Hence, the quality of demographic information can be measured by the degree of consistency among the ten MTurk workers. Let \(E = [e_1, e_2, \ldots, e_k]^T\) be the collection of estimates of one specific demographic attribute (gender or race) by \(k\) (here, \(k = 10\)) MTurk workers. Then the quality value of this demographic attribute can be calculated as

\[
q(E) = \frac{1}{k} \max_{i=1,2,\ldots,c} \{ \sum_j (E_{ij} = i) \},
\]

(4)

where \(c\) is the total number of classes for one demographic attribute. Here, \(c = 2\) for gender (Male and Female); while \(c = 4\) for race (Black, White, Asian, and Unknown). The notation \(\sum_j (E_{ij} = i)\) denotes the number of estimates that are labeled as class \(i\). The quality value range in (4) is in [0, 1].

Quality values for different face media of one subject are shown in Fig. 8. We note that the proposed quality measures give reasonable quality assessment for different input media.

V. EXPERIMENTAL SETUP

The 596 subjects who have at least two images in the LFW database and at least one video in the YTF database (subjects in YTF are a subset of those in LFW) are used to evaluate the performance of face identification on media-as-input. One frontal image per subject is placed in the gallery (one with the highest frontal score from the COTS matcher), and the remaining images are used as probes. All videos for the 596 subjects are used as probes. Table III shows the distribution of number of probe images and videos per subject. The average number of images, videos, and total media instances per subject is 5.3, 2.2, and 7.4, respectively. We further extend the gallery size with an additional 3,653 LFW images (of subjects with only a single image in LFW). In total, the size of the gallery is 4,249. We evaluate five different scenarios depending on the contents of the probe set: (i) single image as probe, (ii) single video track as probe, (iii) multiple images as probe, (iv) multiple video tracks as probe, and (v) multiple images and video tracks as probe. We also take into account the 3D face models and demographic information in the five scenarios.

The state-of-the-art COTS face matcher used in our experiments was one of the top performers in the 2010 NIST Multi-Biometric Evaluation (MBE) [38]. Though the COTS face matcher is designed for matching still images, we apply it to video-to-still face matching via multi-frame fusion to obtain a single score for the video track [18]. In all cases where videos are part of the probe media, we use the mean rule for multi-frame fusion (the \(\max\) fusion rule performed comparably [18]).

B. Open Set Identification

Here, we consider the case when not all probe images or videos have a true mate in the gallery. This is representative of a watch list scenario. The gallery (watch list) consists of videos that have a true mate in the gallery. This is representative of a closed set scenario, where (i) decide whether or not to reject a probe image as not in the gallery, (ii) multiple images, (iii) multiple images and videos.

For all closed set experiments involving still images from LFW, we input eye locations (from [14]) to the COTS face matcher to help with enrollment because the COTS matcher sometimes enrolls a background face that is not the subject of interest in LFW. Against a gallery of approximately 5,000 LFW frontal images, we observed a 2–3% increase in accuracy for Rank-20 and higher by inputting the eye locations. Note that for the YTF video tracks, there are no available ground-truth eye locations for faces in each frame. We report closed set identification results as Cumulative Match Characteristic (CMC) curves.

VI. EXPERIMENTAL RESULTS

A. Pose Correction

We first investigate whether using a COTS 3D face modeling SDK to pose correct a 2D face image prior to matching improves the identification accuracy. The closed set experiments in this section consist of a gallery of 4,249 frontal LFW images and a probe set of 3,143 LFW images or 1,292 YTF videos. Table II (a) shows that the COTS face matcher performs better on face images that have been pose corrected using the Aureus 3D SDK. Matching the original gallery images to the pose corrected probe images (i.e., match score s3) performs the best out of all the four match scores, achieving a 7.25% improvement in Rank-1 accuracy over the baseline (i.e., match score s1). Furthermore, fusion of all the four scores (s1, s2, s3, and s4) with the simple sum rule provides an additional 2.6% improvement at Rank-1.

Consistent with the results for still images, match scores s3 and sum(s1, s2, s3, s4) also provide significant increases in identification accuracy over using match score s1 alone for matching frames of a video clip. The mean fusion is used on scores s1, s2, and s3 or sum to obtain a single score between a video track probe and a gallery image.

Next, we investigate whether the Aureus SDK consolidated 3D models (i.e., n frames of a video track summarized as a single 3D face model rendered at frontal pose) can achieve comparable accuracy to matching all n frames. Table V(a) shows that the accuracy of sum(s3, s4) (i.e., consolidated 3D models matched to original and pose corrected gallery images) provides the same accuracy as matching all n original frames (i.e., score s1 in Table II (b)). However, the accuracy of the consolidated 3D model is slightly lower (≈ 5%) than the mean fusion over all n pose corrected frames (i.e., score s3 in Table II (b)). This means that the consolidated 3D model built from a video track is not able to retain all the discriminatory information contained in the collection of n pose corrected frames.
(b) Video Tracks

(c) Media Collection

Fig. 9. Closed set identification results for different probe sets: (a) multiple still face images, (b) multiple face video tracks, and (c) face media collection (images, videos and 3D face models). Single face image and video track results are plotted in (a) and (b) for comparison. Note that the ordinate scales are different in (a), (b), and (c) to accentuate the difference among the plots.

Fig. 10. A collection of face media for a subject (a) consisting of a single still image, 3D model, and video track improves the rank retrieval of the true mate in the gallery (b). Against a gallery of 4,249 frontal images, the single still image was matched at Rank-438 with the true mate. Including the 3D model along with the still image improved the match to Rank-118, while the entire probe media collection was matched to the true mate at Rank-8.

B. Forensic Identification: Media-as-Input

A summary of results for the various media-as-input scenarios is shown in Fig. 9. For all scenarios that involved multiple probe instances (i.e., multiple images and/or videos), the mean fusion method gave the best result. For brevity, all CMC curves and results that involve multiple probe instances are also obtained via mean fusion. We also investigated the performance of rank-level fusion; the highest-rank fusion performed similar to score-level fusion, while the Borda count method [35] performed worse.

As observed in the previous section, pose correction with the Aureus 3D SDK to obtain scores \( s_3 \) or \( \text{sum}(s_1, s_2, s_3, s_4) \) achieves better accuracies than score \( s_1 \). This is also observed in Figs. 9(a) and 9(b) where scores \( \text{sum}(s_1, s_2, s_3, s_4) \) and \( s_3 \) provide approximately a 5% increase in accuracy over score \( s_1 \) for multiple images and multiple videos, respectively. This improvement is also observed in Fig. 9(c) for matching media that includes both still images and videos, but the improvement is mostly at low ranks (< Rank-50).

Figure 9 shows that (i) multiple probe images and multiple probe videos perform better than their single instance counterparts, but (ii) multiple probe videos actually perform worse than single probe image (see Figs. 9(a) and 9(b)). This is likely due in part to videos in the YTF database being of lower quality than the still images in the LFW database. However, we note that though multiple videos perform poorly compared to still images, there are still cases where the fusion of multiple videos with the still images does improve the identification performance. This is shown in Fig. 9(c); the best result for multiple images is plotted as a baseline to show that the addition of videos to the media collection improves identification accuracy. An example of this is shown in Fig. 10. For this particular subject, there is only a single probe image available that exhibits extreme pose. The additional information provided by the 3D model and video track improves the true match from Rank-438 to Rank-8. In fact, the performance improvement of media (i.e., multiple images and videos) over multiple images alone can mostly be attributed to cases where there is only a single probe image with large pose, illumination, and expression variations.

While Fig. 9 shows that including additional media to a probe collection improves identification accuracies on average, there are cases where matching the entire media collection can
the matching performance. An example is shown in Fig. 11. Due to the fairly low quality of the video tracks, the entire media collection for this subject is matched at Rank-5. This necessitates the use of quality measures to assign a degree of confidence to each media.

C. Quality-based Media Fusion

In this section, we evaluate the proposed quality measures and quality-based face media fusion. As discussed in Section IV, quality measures and quality-based face media fusion can be applied at both within-media layer and across-media layer.

Tables IV (a) and (b) show the closed set identification accuracies of quality-based fusion of match scores ($s_1, \cdots, s_4$) of single image per probe and multiple images per probe, respectively. The performance with sum rule fusion is also provided for comparison. Our results indicate that the proposed quality measures and quality based fusion are able to improve the matching accuracies in both scenarios. Examples where the quality-based fusion performs better than sum rule fusion are shown in Fig. 12 (a). Although in some cases the quality-based fusion may perform worse than sum rule fusion (see Fig. 12 (b)), overall, it still improves the matching performance (see Table IV).

We have also applied the proposed quality measure for 3D face model to select high-quality frames that are used to build a consolidated 3D face model for a video clip. Figure 13 (a) shows two examples where the consolidated 3D models using frame selection with SSIM quality measure (see Sec. IV) gets better retrieval ranks than using all frames. Although, a single value, e.g., the SSIM based quality measure, may not always be reliable to describe the quality of a face image (see Fig. 13 (b)), we still find that frame selection slightly improves the identification accuracy of the consolidated 3D face models at low ranks (see Table V).

D. Forensic Sketch Experiments

In this experiment, we study the effectiveness of forensic sketches in a media collection. For each subject with a forensic sketch, we input the forensic sketch to the COTS matcher to obtain a retrieval rank. Among the 21 subjects for whom we have a sketch, sketches of 12 subjects are observed to perform significantly better than the corresponding low-quality videos. Additionally, when demographic filtering using gender and race is applied, we can further improve the retrieval ranks. Figure 14 shows three examples where the face sketches significantly improved the retrieval ranks compared to low quality videos. The retrieval ranks of sketch and low-quality video fusion are also reported in Fig. 14.

To further demonstrate the efficacy of forensic sketch, we focus on identification of Tamerlan Tsarnaev, the older brother involved in the 2013 Boston marathon bombing. In an earlier study Klontz and Jain [39] showed that while the younger brother, Dzhokhar Tsarnaev, could be identified at Rank-1 based on his probe images released by the authorities, the
To simulate a large-scale forensic investigation, the three gallery images of Tamerlan Tsarnaev were added to a background set of one million mugshot images of 324,696 unique subjects from the PCSO database. Particularly due to the occlusion of eyes, the probe images are difficult for the COTS face matcher to identify (though they can be enrolled with manually marked eye locations), as shown in Table VI. However, the rank retrieval for the sketch ($I_c$ in Fig. 15) is much better compared to the two probe images ($I_a$ and $I_b$ in Fig. 15), with the best match at Rank-6,259 for max fusion of multiple images of Tamerlan Tsarnaev ($I_x$, $I_y$, and $I_z$) in the gallery. With demographic filtering [40] (white male in the age range of 20 to 30 filters the gallery to 54,638 images of 13,884 subjects), the sketch is identified with gallery image $I_x$ (a mugshot) in Fig. 15 at Rank-112. Again, score fusion of multiple images per subject in the gallery further lowers the retrieval to Rank-71. The entire media collection (here, $I_a$, $I_b$ and $I_c$ in Fig. 15) is matched at Rank-82 against the demographic-filtered and multiple image-fused gallery.

17 See [39] for the sources of the gallery images.
19 “I was living in Costa Rica at the time that event took place and while I saw some news coverage, I didn’t see much and I don’t know what he actually looks like. The composite I am working on is 100% derived from what I am able to see and draw from the images you sent. I can’t make up information that I can’t see, so I left his hat on and I can only hint at eye placement.” - Jane Wankmiller, forensic sketch artist, Michigan State Police.

To simulate a large-scale forensic investigation, the three gallery images of Tamerlan Tsarnaev were added to a background set of one million mugshot images of 324,696 unique subjects from the PCSO database. Particularly due to the occlusion of eyes, the probe images are difficult for the COTS face matcher to identify (though they can be enrolled with manually marked eye locations), as shown in Table VI. However, the rank retrieval for the sketch ($I_c$ in Fig. 15) is much better compared to the two probe images ($I_a$ and $I_b$ in Fig. 15), with the best match at Rank-6,259 for max fusion of multiple images of Tamerlan Tsarnaev ($I_x$, $I_y$, and $I_z$) in the gallery. With demographic filtering [40] (white male in the age range of 20 to 30 filters the gallery to 54,638 images of 13,884 subjects), the sketch is identified with gallery image $I_x$ (a mugshot) in Fig. 15 at Rank-112. Again, score fusion of multiple images per subject in the gallery further lowers the retrieval to Rank-71. The entire media collection (here, $I_a$, $I_b$ and $I_c$ in Fig. 15) is matched at Rank-82 against the demographic-filtered and multiple image-fused gallery.

Fig. 13. Retrieval ranks using consolidated 3D face models (built from video tracks). Frame selection with SSIM quality measure (see Sec. IV) prior to building the 3D model (a) improves and (b) degrades the identification accuracy with the consolidated 3D face model. However, overall, frame selection using the proposed quality measure based on SSIM improves the accuracy with the consolidated 3D face model. However, overall, frame selection using the proposed quality measure based on SSIM improves the accuracy with the consolidated 3D face model.

Fig. 14. Three examples where the face sketches drawn by a forensic artist after viewing the low-quality videos improve the retrieval rank. The retrieval ranks without and with combining the demographic information (gender and race) are given in the form of #(#).

Fig. 15. Face images used in our case study on identification of Tamerlan Tsarnaev, one of the two suspects of the 2013 Boston Marathon bombings. Probe ($I_a$, $I_b$) and gallery ($I_x$, $I_y$, and $I_z$) face images are shown. $I_c$ is a face sketch drawn by a forensic sketch artist after viewing $I_a$ and $I_b$, and a low quality video frame from a surveillance video.
E. Watch List Scenario: Open Set Identification

We report the DIR vs. FAR curves of open set identification in Figs. 16 (a) and (b). With a single image or single video per subject in the gallery, the DIRs at 1% FAR are about 25%, and 10% for still image probe and video clip probe, respectively. This suggests that a large percentage of probe images or video clips that are matched to their gallery true mates at a low rank in a closed set identification scenario, can no longer be successfully matched in an open set scenario. Of course, this comes at the benefit of a much lower false alarms than in the closed set identification. The proposed face media collection based matching still shows improvement than a single media based matching. For example, at 1% FAR, face media collection based matching leads to about 20% and 15% higher DIRs for still image and video clip probes, respectively.

F. Large Gallery Results

1) Extended PCSO Gallery: In order to simulate the large-scale nature of operational face identification, we extend the size of our gallery by including one million face images from the PCSO database. We acknowledge that there may be a bias towards matching between LFW gallery and LFW probe images versus matching PCSO gallery with LFW probe images. This bias is likely due to the fact that the gallery face images in LFW are not necessarily frontal with controlled illumination, expression, etc., while the background face images from PCSO are mugshots of generally cooperative subjects.

The extended gallery set with 1M face images makes the face identification problem more challenging. Figure 16(c) gives the media collection based face identification accuracies with 1M background face images. A comparison between Fig. 16 (c) and Fig. 9 shows that the proposed face media collection based matching generalizes well to a large gallery set.

VII. CONCLUSIONS

In this paper, we studied face identification of persons of interest in unconstrained imaging scenarios with uncooperative subjects. Given a face media collection of a person of interest (i.e., face images and video clips, 3D face models built from image(s) or video frame(s), face sketch, and demographic information), we have demonstrated an incremental improvement in the identification accuracy of a COTS face matching system. This is of great value to forensic investigations and "lights out" watch list operations, as matching the entire collection outputs a single ranked list of candidate identities, rather than a ranked list for each face media sample. Evaluations are provided in the scenarios of closed set identification, open set identification, and identification with a large gallery. Our contributions can be summarized as follows:

1) A collection of face media, such as image, video, 3D face model, face sketch, and demographic information, on a person of interest improves identification accuracies, on average, particularly when individual face media samples are of low quality for face matching.
2) Pose correction of unconstrained 2D face images and video frames (via 3D face modeling) prior to matching improves the identification accuracy of a state of the art COTS face matcher. This improvement is especially significant when match scores from rendered pose corrected images are fused with match scores from original face imagery.

3) While a single consolidated 3D face model can summarize the entire video track, matching all the pose corrected frames of a video track performs better than the consolidated model.

4) Quality based fusion of match scores of different media types performs better than fusion without incorporating the quality.

5) The value of forensic sketch drawn based on low quality videos or low quality images of the suspect is demonstrated in the context of one of the Boston bombing suspects and YTF video tracks.

Future work involves investigation of more effective face quality measures to further boost the performance of fusion for matching a media collection. A reliable face quality value will prevent forensic analysts from having to attempt all possible combinations of face media matching. Another important problem is to improve 3D model construction from multiple still images and/or video frames.

ACKNOWLEDGEMENTS

The sketches drawn from the video were prepared by Jane Wankmiller and Sarah Krebs, sketch artists with the Michigan State Police.
